ASSISTANT COMMISSIONER FOR PATENTS
Washington, D.C. 20231

Sir:

Transmitted herewith for filing is the patent application of

Inventor: ICHIRO FUJIWARA

For: NONVOLATILE SEMICONDUCTOR MEMORY DEVICE AND PROCESS OF
PRODUCTION AND WRITE METHOD THEREOF

Enclosed are:

- Specification and Claim(s).
- Oath or Declaration (unexecuted).
- Eighteen sheet(s) of drawings.
- An assignment of the invention to _____.
- Copy of _____ priority application(s).
- Associate Power of Attorney.

The fee has been calculated as shown below:

CLAIMS AS FILED				
FOR	NUMBER FILED	NUMBER EXTRA	RATE	BASIC FEE \$380/\$760
TOTAL CLAIMS	51-20	31	X \$ 9 \$18	\$558.00
INDEP. CLAIMS	6-3	3	X \$39 \$78	\$234.00
Fee for Multiple Dependent Claims \$130/\$260				0
			TOTAL FILING FEE	\$1552.00

- A Preliminary Amendment is attached.
- Verified Statement claiming small entity status is enclosed.
- Charge \$ 1552.00 to Deposit Account No. 18-0013 to cover the filing fee. A duplicate copy of this sheet is enclosed.
- The Commissioner is hereby authorized to charge any fees under 37 C.F.R. 1.16 or 1.17 which may be required during the entire pendency of this application, or to credit any overpayment, to Deposit Account No. 18-0013. A duplicate copy of this sheet is enclosed.
- A check in the amount of \$____ cover the filing fee is enclosed.
- Charge \$_____ to Deposit Account No. 18-0013 to cover the recordal fee. A duplicate copy of this sheet is enclosed.
- Applicant's undersigned attorney may be reached by telephone in our Washington D.C. Office at

(202) 955-3750.

All correspondence should be directed to our below listed address.

NONVOLATILE SEMICONDUCTOR MEMORY DEVICE AND PROCESS OF
PRODUCTION AND WRITE METHOD THEREOF

5 **BACKGROUND OF THE INVENTION**

1. **Field of the Invention**

The present invention relates to a nonvolatile semiconductor memory device providing planarly dispersed charge storing means (for example, charge traps in a 10 nitride film in a MONOS type or MNOS type transistor, charge traps near the interface of a top insulating film and nitride film, small particle size conductors, etc.) inside of a gate insulating film between a channel forming region and gate electrode of a memory transistor 15 and basically operating to electrically inject charges (electrons or holes) into the charge storing means to store the same or to drain the same and to a process for production and write method for the same.

2. **Description of the Related Art**

20 As a nonvolatile semiconductor memory, a floating gate (FG) type nonvolatile semiconductor memory where charge storing means (floating gates) for holding charges are planarly dispersed, and a metal-oxide nitride-oxide semiconductor (MONOS) type nonvolatile 25 semiconductor memory for example where the charge storing

means are planarly dispersed are known.

In a MONOS type nonvolatile semiconductor memory, carrier traps in a nitride film (Si_xN_y ($0 < x < 1$, $0 < y < 1$)) mainly responsible for holding charges or at a boundary (an interface) between a top oxide film and the nitride film spread out spatially dispersedly (that is, in the planar direction and thickness direction), so the charge retention characteristic is dependent on the energy and spatial distribution of the charges captured by the carrier traps in the Si_xN_y film.

When leakage current paths are locally generated in the tunnel insulating film, in the FG type nonvolatile semiconductor memory, a large number of the charges pass through the leakage current paths and the 15 charge retention characteristic tends to decline, while in the MONOS type nonvolatile semiconductor memory, since the charge storing means are spatially dispersed, the local charges around the leakage current paths pass through the leakage current paths and only local leakage 20 occurs so the charge retention characteristic of the storage element as a whole does not easily fall.

Therefore, in the MONOS type nonvolatile semiconductor memory, the problem of the reduction of the charge retention characteristic due to a reduction in the thickness of the tunnel insulating film is not as serious

卷之三

as that in the FG type nonvolatile semiconductor memory. Therefore, the scaling of a tunnel insulating film in a fine memory transistor with an extremely short gate length is better in the MONOS type nonvolatile 5 semiconductor memory than the FG type nonvolatile semiconductor memory.

In a MONOS type nonvolatile semiconductor memory or other nonvolatile semiconductor memory with planarly dispersed charge storing means of the memory 10 transistors, it is essential to realize a one-transistor type of cell structure in order to reduce the cost per bit, increase the degree of integration, and realize a large-sized nonvolatile semiconductor memory.

In a MONOS type nonvolatile semiconductor 15 memory or other nonvolatile semiconductor memory of the related art, however, the mainstream configuration has been for a two-transistor cell with a selected transistor connected to the memory transistor. At the present time, various studies are underway for establishment of single 20 transistor cell technology.

In order to establish such single transistor cell technology, it is necessary to optimize the device structure, primarily the gate insulating film including the charge storing means, and improve the reliability and 25 also to improve the disturbance characteristic. Further,

as one measure for improving the disturbance characteristic of a MONOS type nonvolatile semiconductor memory, studies are being conducted on setting the tunnel insulating film thicker (1.6 nm to 2.0 nm).

5 Further, in order to reduce the cost per bit of a nonvolatile semiconductor memory and increase the integration density, it is necessary to miniaturize the memory cell and also reduce the area of the surrounding circuits. In reducing the area of surrounding circuits, 10 it is important to reduce the write voltage and erase voltage from the viewpoint of ensuring the reliability along with miniaturization of the memory cell and reducing the circuit load of the surrounding circuits. Further, even in a system LSI, where there has been 15 active development going on in recent years, it is becoming important to reduce the operating voltage from the viewpoint of mounting together with logic circuits.

20 Summarizing the problem, in a MONOS type nonvolatile semiconductor memory or other nonvolatile semiconductor memory with planarly dispersed charge storing means of the related art, setting the tunnel insulating film relatively thick in order to improve the disturbance characteristic limits the reduction of the operating voltage. That is, in a nonvolatile 25 semiconductor memory of the related art, there is a

657044-9/207650

tradeoff between making the tunnel insulating film thicker and reducing the operating voltage while maintaining a fast operating rate. Due to this, it suffers from the problem that it is not possible to 5 simultaneously improve the disturbance characteristic and reduce the operating voltage.

SUMMARY OF THE INVENTION

An object of the present invention is to provide a 10 nonvolatile semiconductor memory such as a MONOS type nonvolatile semiconductor memory which operates by storing charges in planarly dispersed carrier traps and which has a better scaling of the tunnel insulating film than the FG type nonvolatile semiconductor memory, where 15 it is possible to reduce the operating voltage while maintaining an excellent disturbance characteristic, and a process for the production of the same.

Another object of the present invention is to provide a write method in a nonvolatile semiconductor 20 memory, including a bias setting method preferable to the cell structure.

According to a first aspect of the present invention, there is provided a nonvolatile semiconductor memory comprising: a substrate; and a plurality of memory 25 transistors formed in the substrate and arranged in a

word direction and a bit direction, each memory
transistor including: a semiconductor channel forming
region formed in the substrate; a gate insulating film
formed on the semiconductor channel forming region and
5 comprising a Fowler-Nordheim (FN) type tunneling film
which has a FN type tunneling electroconductivity and
contains material having a dielectric constant greater
than that of silicon oxide; a gate electrode formed on
the gate insulating film; and a charge storing means,
10 formed in the gate insulating film, and facing to the
surface of the channel forming region.

The FN tunneling film comprises any one of a nitride
film, an oxynitride film, and aluminum oxide film, a
tantalum pentaoxide film and a BST (BaSrTiO₃) film,
15 having an FN tunneling electroconductivity.

The gate insulating film includes a buffer layer
formed between the FN tunneling film and the channel
forming region and suppressing an interface trap level.

The gate insulating film may comprise a Pool-Frenkel
20 (PF) type film including any one of a nitride film, an
oxynitride film, and aluminum oxide film, a tantalum
pentaoxide film and a BST (BaSrTiO₃) film, having an PN
type electroconductivity.

The nonvolatile semiconductor memory device may
25 further comprises a pull-up electrode in the vicinity of

the gate electrode or a wiring layer connected to the gate electrode, via a dielectric film; and a pull-up gate bias means for applying a voltage to the pull-up electrode.

5 a plurality of gate electrode of the plurality of
memory transistors are connected to a plurality of word
lines, and a selected transistor is connected between the
pull-up gate bias means and the pull-up electrode, the
pull-up gate bias means supplying a voltage having a
10 polarity same to a polarity of a boosting voltage for
boosting the precharged word line by a capacitance
coupling.

The pull-up electrode may be arranged in the vicinity of an upper portion of the gate electrode or a connection layer connected to the gate electrode, via the dielectric film.

20 Each memory transistor comprises a source region contracted to the channel forming region, and a drain region spaced to the source region and contacted to the channel forming region, a plurality of gate electrodes of the plurality of memory transistors are connected to a plurality of word lines, the source region and drain region of each memory transistor are connected to a common line in a bit direction, electrically insulated to
25 and intersecting to the word line. The nonvolatile

semiconductor memory device further comprises a write inhibit voltage supply means for supplying a reverse-biased voltage to the source region and/or the drain region of the memory transistor the gate electrode of 5 which is connected to the word line selected at a writing, through the common line, to make the source region and/or the drain region in a reverse-biased state to the channel forming region, and a non-selected word line biasing means for supplying a voltage to a non- 10 selected word line at the writing, a polarity of the voltage being a polarity making the non-selected word line in a reverse biased state to the channel forming region.

The write inhibit voltage supply means supplies the 15 reverse bias voltage to the source region and/or the drain region to make a bias a voltage of the memory transistor connected to the selected word line to thereby prevent an erroneous write and/or an erroneous erase.

The non-selected word line biasing means supplies a 20 voltage having a polarity for reverse-biasing to the non-selected word line to make a bias a voltage of the memory transistor connected to the non-selected word line to thereby prevent an erroneous write and/or an erroneous erase.

25 The non-selected word line biasing means a biases

the gate electrode to the source region so that a voltage of the gate electrode becomes a low level equal or lower than an inhibit gate voltage.

When the reverse bias voltage is supplied to the
5 channel forming region while the gate electrode and the channel forming region of the memory transistor are kept at a same potential level, depletion layers extend from the source region and drain region to the channel forming region to merge them.

10 The gate length of the memory transistor is shorter than a gate length given by, when the reverse bias voltage is supplied while the gate electrode and the channel forming region are kept at a same potential level, a merged depletion layers extended from the source
15 region and the drain region to the channel forming region.

Each memory transistor comprises a source region contacted to the channel forming region, and a drain region spaced to the source region and contacted to the
20 channel forming region, and the nonvolatile semiconductor memory device comprises a source line commonly connecting the plurality of source regions of the plurality of memory transistors in a bit direction.

A bit line commonly connects the plurality of drain
25 regions of the plurality of memory transistors in the bit

direction, and a word line commonly connects the plurality of gate electrodes of the plurality of memory transistors in a word direction.

Each memory transistor comprises a source region 5 contacted to the channel forming region, and a drain region spaced to the source region and contacted to the channel forming region, and the nonvolatile semiconductor memory device comprises sub source lines commonly connecting the plurality of source regions of the 10 plurality of memory transistors in a bit direction. a main source line commonly connects the sub source lines in the bit direction, sub bit lines commonly connects the plurality of drain regions of the plurality of memory transistors in the bit direction, a main bit line 15 commonly connecting the sub bit line in the bit direction, and a word line commonly connects the plurality of gate electrodes of the plurality of memory transistors in a word direction. A selected memory transistor is connected between the sub source line and the 20 main source line and between the sub bit line and the main bit line.

The plurality of memory transistors are connected in series between a first selected transistor connected to a bit line and a second selected transistor connected to a 25 common potential line.

660074-3/07/1990

Each memory transistor comprises a source region contacted to the channel forming region, and a drain region spaced to the source region and contacted to the channel forming region. The nonvolatile semiconductor

5 memory device comprises a plurality of element separation regions for isolating the respective memory transistors by insulation, a common line commonly connecting the source regions or the drain regions in a bit direction, and a word line connecting the plurality of gate

10 electrodes in a word direction. The plurality of element separation regions are formed as lines along the bit direction and spaced each other, and the common line intersects and is electrically isolated to the word line, is connected to one of the source region or the drain

15 region, and is wired on the element separation regions by avoiding a wiring passing on another region of the source region or the drain region which is not connected to the common line.

The plurality of element separation regions are

20 formed as parallel strips having a width approximately equal to that of the word line, adjacent strips being spaced as adjacent word lines, a self-aligned contact hole is formed on the source region and the drain region by using a sidewall insulation layer formed on sidewalls

25 of the word line, and the common line wired on the

element separation regions is commonly connected to the one region through the self-aligned contact hole and is wired by a winding manner in the bit direction.

The charge storing means does not have conductivity
5 as a whole facing to the channel forming region when charges are not moved to the outside of the memory transistor.

The gate insulating film comprises a tunneling insulating film formed on the channel forming region, and
10 a nitride film or an oxide nitride film, formed on the tunneling insulating film.

The gate insulating film comprises a tunneling insulating film formed on the channel forming region, and conductors including small sized conductive material,
15 formed on the tunneling insulating film as the charge storing means and isolated each other.

According to a second aspect of the present invention, there is provided a process of producing the nonvolatile semiconductor memory, including steps of:
20 forming a drain region, a source region and a channel forming region arranged between the drain region and the source region and contacted to them; forming a gate insulating film including a charge storing means formed on and facing the surface of the channel forming region;
25 and forming a gate electrode on the gate insulating film,

667077-9/2016-010

the gate insulating film formation step including a step of forming a Fowler-Nordheim (FN) type tunneling film comprising material having an FN tunneling electroconductivity and having a dielectric constant 5 larger than that of silicon oxide, and the FN tunneling film forming step including a step of heating the FN tunneling film at a high temperature in an atmosphere of reduction gas and/or oxidation gas.

The process further includes a step of forming a 10 buffer layer formed between the FN tunneling film and the channel forming region and suppressing an interface trap level, before forming the FN tunneling film.

A process of further include a step of forming a 15 Pool-Frenkel (PF) type film including any one of a nitride film, an oxynitride film, and aluminum oxide film, a tantalum pentaoxide film and a BST (BaSrTiO₃) film, having an PF electroconductivity, on the FN tunneling film.

A process of further include a step of forming a PN 20 film on the FN tunneling film via the buffer layer, the PN film comprising any one of a nitride film, an oxynitride film, an aluminum oxide film, a tantalum pentaoxide film and a BST (BaSrTiO₃) film, having a PF electroconductivity.

25 According to a third aspect of the present

060077-907560

invention, there is provided a method of writing data into the nonvolatile semiconductor memory device, including a step of applying a voltage to the pull-up electrode to raise a potential of the gate electrode.

5 A method includes a step of applying a program voltage equal or lower than 10V, to a gate electrode of the selected memory transistor.

A method includes the steps of: supplying a reverse-biased voltage to the source region and/or the

10 drain region of the memory transistor the gate electrode of which is connected to the word line selected at a writing, through the common line, to make the source region and/or the drain region in a reverse-biased state to the channel forming region, and supplying a voltage to
15 a non-selected word line at the writing, a polarity of the voltage being a polarity making the non-selected word line in a reverse-biased state to the channel forming region.

A method includes a step of supplying the
20 reverse-bias voltage to the source region and/or the drain region to make a bias a voltage of the memory transistor connected to the selected word line to thereby prevent an erroneous write and/or an erroneous erase.

A method includes a step of supplying a voltage
25 having a polarity for reverse-biasing to the non-selected

word line to make a bias a voltage of the memory transistor connected to the non-selected word line to thereby prevent an erroneous write and/or an erroneous erase.

5 A method includes a step of biasing the gate electrode to the source region so that a voltage of the gate electrode becomes a low level equal or lower than an inhibit gate voltage.

When the reverse bias voltage is supplied to the 10 channel forming region, the gate electrode and the channel forming region of the memory transistor are applied by a same voltage.

The reverse bias voltage is applied to the source region via a source line commonly connecting the source 15 regions in the bit direction, and/or, the drain region via a bit line commonly connecting the drain regions in the bit direction, and the voltage having a polarity for reverse-biasing is applied via the word line commonly connecting the gate electrodes in the word direction.

20 A program voltage is applied to the gate electrode, and a voltage is applied to the pull-up electrode of the selected memory transistor.

A voltage having a polarity for reverse-biasing is applied to the non-selected word line, the 25 reverse-biasing voltage is applied to the source region

and/or the drain region of the memory transistor connected to the selected word line, a program voltage is applied to the selected word line, and a voltage is applied to the pull-up electrode.

5

BRIEF DESCRIPTION OF THE DRAWINGS

These and other objects and features of the present invention will become more apparent from the following description of the preferred embodiments given with

DESCRIPTION OF THE PREFERRED EMBODIMENTS

First Embodiment

Figure 1 is a view of the general configuration of a
20 divided source line NOR type nonvolatile semiconductor
memory according to a first embodiment of the present
invention.

In the nonvolatile semiconductor memory 90 of the first embodiment, each of the memory cells of a NOR type 25 memory cell array is comprised of a single memory

transistor. As shown in Fig. 1, the memory transistors M11 to M22 are arranged in an array. Word lines, bit lines, and divided source lines are laid between the adjacent transistors. That is, the drains of the memory 5 transistors M11 and M12 adjoining each other in the bit direction are connected to the bit line BL1, while the sources are connected to the source line SL1. Similarly, the gates of the memory transistors M12 and M22 adjoining each other in the word direction are connected to the 10 word line WL2.

The cell arrangement and the interconnection of cells are repeatedly in this way in the memory cell array as a whole.

Figure 2 is a general plan view of a fine NOR type 15 memory cell array using self-alignment and serpentine (meander arranged) source lines as a specific example of the cell arrangement pattern of the first embodiment.

In this fine NOR type memory cell array 70, longitudinal strip trenches or LOCOS or other element 20 separation (isolation) regions 71 are arranged on the surface of a not shown p-well at equal intervals in the bit direction (longitudinal direction of Fig. 2). Word lines WL_{m-2}, WL_{m-1}, WL_m, and WL_{m+1} are arranged at equal intervals substantially perpendicular to the element 25 separation regions 71. Each of the word lines, as

explained below, is comprised of a stacked film structure of a tunnel insulating film, nitride film, top insulating film, and gate insulating film. While not particularly illustrated, for example, the same pattern of pull-up lines 5 are arranged on the not shown word lines through a dielectric film.

In the active regions in the intervals between the element separation regions, for example, an n-type impurity is doped at a high concentration to alternately 10 form source regions and drain regions in the intervals between the word lines. These source regions and drain regions are defined in size in the word direction (lateral direction of Fig. 2) only by the intervals between the trenches or LOCOS or other element separation 15 regions 71 and are defined in the bit direction only by the intervals between the word lines. Therefore, the source regions and drain regions can be formed extremely uniformly in size and arrangement since almost no mask alignment error is introduced.

20 Around the word lines, by just forming side walls, contact holes for connecting bit lines and contact holes for connecting source lines are formed with respect to the source regions and drain regions by simultaneously applying two self-aligned contact forming steps. Further, 25 the above process does not require a photomask.

690077-3707660

Therefore, as explained above, not only the source regions and drain regions are uniform in size and arrangement, but also the contact holes for connection of the bit lines or source lines formed by self-alignment 5 two-dimensionally become extremely uniform in size as well. Further, the contact holes have substantially the maximum extent of size with respect to the area of the source regions and drain regions.

The source lines SL_{n-1} , SL_n , and SL_{n+1} arranged in the bit direction are arranged in a serpentine (meander) fashion on the element separation regions 71 and source regions while avoiding the drain regions and are connected to the lower layer source regions through the contact holes for connection of the source lines. The bit lines BL_{n-1} , BL_n , and BL_{n+1} are arranged on the source lines through a second interlayer insulating film at equal intervals. The bit lines are positioned above the active regions and are connected through the contact holes for connection of the bit lines to the lower layer drain regions.

In such a configuration of a cell pattern, as explained above, since the source regions and drain regions can be formed without being affected much by mask alignment or since the contact holes for bit line connection and contact holes for source line connection

are formed by applying two self-alignment steps, the contact holes do not act as elements restricting the reduction of the cell area, it is possible to arrange sources at the minimum line width F of the limit of the wafer process, and there is almost no wasted space, so it is possible to realize an extremely small cell area close to $6F^2$.

Figure 3 is a sectional view of the element structure of a MONOS type memory transistor according to the first embodiment.

In Fig. 3, reference numeral 1 represents a silicon wafer or other semiconductor substrate having an n-type or p-type conductivity, 1a represents a channel forming region, and 2 and 4 represent the source region and drain region of the memory transistor.

In the present specification, the "channel forming region" means the region where a channel is formed for conduction of electrons or positive holes inside the surface side. The "channel forming region" in the first embodiment corresponds to the portion sandwiched between the source region 2 and the drain region 4 inside the semiconductor substrate.

The source region 2 and the drain region 4 are regions of a high conductivity formed by doping an impurity of an opposite (inversed) conductivity to the

channel forming region 1a at a high concentration in the semiconductor substrate 1. There are various forms of this. Normally, it is often possible to provide a low concentration impurity region called a "lightly doped 5 drain (LDD)" region at positions of the substrate where the source region 2 and the drain region 4 are close to the channel forming region 1a.

On the channel forming region 1a is stacked a gate electrode 8 of the memory transistor through a gate 10 insulating film 6. The gate electrode 8 generally is comprised of polycrystalline silicon made conductive by doping with a p-type impurity or an n-type impurity at a high concentration (doped poly-Si) or a stacked film of doped poly-Si and a high melting point metal silicide.

15 The gate insulating film 6 of the first embodiment is comprised, in order from the bottom layer, of a tunnel insulating film 10, nitride film 12, and top insulating film 14.

The tunnel insulating film 10 is a nitride film 20 having Fowler-Nordheim (FN) tunneling electroconductivity (FN tunnel nitride film). This FN tunnel nitride film is a silicon nitride film fabricated by for example a jet vapor deposition (JVD) method or a method of heating and changing the chemical vapor deposition (CVD) film in an 25 atmosphere condition of a reducing or oxidizing gas

(hereinafter referred to as the heat FN tunneling method) or a film comprised mainly of silicon nitride (for example, a silicon oxynitride film).

While a silicon nitride film fabricated by normal CVD exhibits a Pool-Frenkel type (PF type) electroconductivity, an FN tunnel nitride film exhibits an FN type electroconductivity since the carrier trap effect in the film is reduced compared with a nitride film fabricated by normal CVD. Therefore, the electrons 10 are conducted through the tunnel insulating film 10 in a write operation using demodified FN tunneling.

The thickness of the tunnel insulating film (FN tunnel nitride film) 10 can be set in the range of 2.0 nm to 5.0 nm in accordance with the application of the 15 nonvolatile semiconductor memory. Here, it is set to 3.0 nm.

The nitride film 12 is comprised of a silicon nitride (Si_xN_y ($0 < x < 1$, $0 < y < 1$)) film of 3.0 nm. This nitride film is fabricated for example by low pressure CVD (LP-CVD). A large amount of carrier traps are 20 included in the film. The nitride film 12 exhibits a PF type electroconductivity. Therefore, the nitride film 12 has a completely different quality and mechanism (phenomenon) of electroconduction from the lower layer 25 tunnel insulating film 10.

The top insulating film 14 is formed by heat oxidizing the nitride film after its formation since it is necessary to form deep carrier traps at a high density near the boundary (interface) with the nitride film 12.

5 When the top insulating film 14 is formed by CVD, the traps are formed by heat treatment. The thickness of the top insulating film 14 must at the minimum be 3.0 nm, preferably 3.5 nm, in order to effectively prevent holes from being injected from the gate electrode 8 and prevent

10 a reduction in the data write life.

Next, an example of the process of production of a memory transistor of such a configuration will be explained briefly focusing on the process for forming a gate insulating film.

15 First, explaining the basic general flow of the process of production, element separation regions are formed on a prepared semiconductor substrate 1, a well is formed, ions are injected for adjustment of the threshold voltage if necessary, then a stacked pattern of the gate

20 insulating film 6 and gate electrode 8 is formed on an active region of the semiconductor substrate 1, the interlayer insulating film is formed, contact holes are formed, source and drain electrodes are formed, and if necessary upper layer interconnections are formed over

25 the interlayer insulating film, an overcoat is formed,

and pads are opened so as to complete the nonvolatile memory transistor.

In the step for formation of the gate insulating film 6, first the JVD method or heat FN tunneling method 5 is used to form the FN tunnel nitride film 10 to for example about 3 nm.

In the JVD method, Si and N molecules or atoms are discharged from a nozzle into a vacuum at an extremely high speed, the high speed flow of the molecules or atoms 10 is guided onto the silicon substrate, and for example a silicon oxynitride film is deposited.

In the heat FN tunneling method, first, as processing before fabrication of the FN tunnel nitride film 10, the semiconductor substrate 1 is heated for 15 example in an NO atmosphere at 800°C for 20 seconds or so. Next, for example, LP-CVD is used to deposit a silicon nitride (SiN) film. Next, the CVD film is heat treated in for example an ammonia (NH₃) gas atmosphere at 950°C for 30 to 60 seconds, then heat treated in an N₂O 20 gas atmosphere at 800 to 850°C for 30 seconds to 1 minute to change the SiN film, which had been a PF film exhibiting PF conductivity directly before formation of the film by CVD, to an FN tunnel film.

On the FN tunnel nitride film 10 fabricated in this 25 way is thickly deposited a nitride film 12 by LP-CVD to

give a final thickness of 3.0 nm. This CVD is for example performed using a gas comprised of a mixture of dichlorosilane (DCS) and ammonia at a substrate temperature of 650°C. Here, if necessary, an increase in

5 the roughness of the finished film surface may be suppressed by optimizing the pretreatment of the underlying surface (wafer pretreatment) and film forming conditions. In this case, if the wafer pretreatment is not optimized, the surface morphology of the silicon 10 nitride film will be poor and accurate measurement of thickness will not be possible, so the wafer pretreatment may be sufficiently optimized, then the thickness of the film set in consideration of the loss of the silicon nitride film in the next heat oxidation step.

15 The nitride film 12 formed has many carrier traps and exhibits a PF electroconductivity.

The surface of the nitride film 12 formed is for example oxidized by heat oxidation to form a top insulating film 14 to a thickness of 3.5 nm or so. This heat oxidation is for example performed in an H_2O atmosphere at a furnace temperature of 950°C. As a result, deep carrier traps with a trap level (energy difference from conduction band of silicon nitride) of not more than 2.0 eV or so are formed at a density of about 1 to $2 \times 10^{13} \text{ cm}^{-2}$. Further, a heat oxidized silicon

film (top insulating film 14) is formed to a thickness of 1.6 nm with respect to a nitride film 12 of 1 nm. The thickness of the underlying nitride film is reduced by this rate. The final thickness of the nitride film 12 5 becomes 3 nm.

After the gate insulating film 6 is formed in this way, the film forming the gate electrode 8 is formed and the conductive film for forming the gate electrode 8 and the gate insulating film 6 are continuously etched by for 10 example reactive ion etching (RIE). This completes the patterning of the gate electrodes, then the above steps are gone through to complete the nonvolatile memory transistor.

When forming the tunnel oxide film in the ONO film 15 of the MONOS type nonvolatile memory transistor (tunnel oxide film/nitride film/top oxide film) to a thickness of for example 3 nm or so, typical values of the specification of the thickness of the ONO film up to now have been 3.0/5.0/3.5 nm. The ONO film has a thickness of 20 9 nm converted to values of a silicon oxide film.

On the other hand, the MONOS type nonvolatile memory transistor according to the first embodiment has the advantage that it is possible to form the intermediate nitride film 12 thinner by using an FN tunnel nitride 25 film for the tunnel insulating film 10. That is, the

thickness specifications of the gate insulating film 6 can be made for example an FN tunnel nitride film of 3.0 nm, a nitride film of 3.0 nm, and a top oxide film of 3.5 nm. In this case, since the dielectric constant of 5 silicon nitride is about two times that of silicon oxide, the value estimated to that of silicon oxide becomes 6.5 nm, that is, this means the reduction of 30% to the earlier device. This is believed to be because if an FN tunnel nitride film is used for the tunnel insulating 10 film 10, the number of carrier traps in the tunnel insulating film 10 and at the boundary (interface) between the tunnel insulating film 10 and nitride film 12 sharply falls, so deep carrier traps formed near the boundary (interface) between the nitride film 12 and the 15 top insulating film 14 are used for storing charges more efficiently than in the past.

In this way, in the first embodiment, the tunnel insulating film 10, which had generally been 1.6 nm to 2.0 nm or so in thickness in the past, is set relatively 20 thick to improve the disturbance characteristic and an FN tunnel insulating film is used for the tunnel insulating film 10 so as to reduce the effective thickness of the gate insulating film 6 and, as a result, enable an increase of the thickness of the tunnel insulating film 25 and reduction of the operating voltage.

Further, there is also the method of forming a top insulating film by directly heat oxidizing the FN tunnel nitride film, a concept different from the method of formation of a transistor illustrated in Fig. 3. The 5 structure of this modification is shown in Fig. 4.

In the nonvolatile memory transistor shown in Fig. 4, a gate insulating film 25 comprises a buffer layer 24, an FN tunnel nitride film 10 and a top insulating film 14, but does not have the nitride film 12 deposited by 10 LP-CVD and exhibiting a PF electroconductivity. The top insulating film 14 is directly formed on the FN tunnel nitride film 10. The buffer layer 24 is a thin PF film formed by heat nitridation of the substrate surface and acts to suppress the generation of the boundary 15 (interfacial) energy level at the substrate surface. The buffer layer 24 eases the strain on the FN tunnel nitride film 10 and therefore there is no increase in the number of carrier traps of the FN tunnel nitride film 10 due to the strain.

20 The FN tunnel nitride film 10 has a relatively low density of carrier traps in the film compared with a PF film, so the carrier traps formed at the boundary (interface) with the top insulating film 14 are mainly responsible for holding the charges. When the number of 25 carrier traps for holding charges is sufficient, it is

possible to make the thickness of the PF film, reduced in thickness down to 3 nm in the above embodiment, 0, that is, to eliminate it.

5 The nonvolatile memory transistor shown in Fig. 4 can operate with a further lower voltage compared with Fig. 3 by just eliminating the PF film (nitride film 12 or oxynitride film 22).

In the first embodiment, as the means for further improving the disturbance characteristic, as shown in 10 Fig. 1, provision is made of a write inhibit voltage supply circuit 92 which is connected to common lines in the bit direction and supplies a reverse bias voltage to the source regions 2 and/or drain regions 4 of nonselected memory transistors and a nonselected word 15 line bias circuit 94 which is connected to the word lines and supplies a voltage giving a reverse bias from the channel forming regions 1a to the gate electrodes 8 of nonselected cells.

Here, a "common line" means a line which commonly 20 and directly connects or capacity-couples the source regions or drain regions of a plurality of memory transistors in the bit direction (column direction) and may be for example a bit line or source line and also a so-called booster plate etc. Figure 1 shows the case of 25 the nonvolatile semiconductor memory where the common

lines are bit lines and source lines.

Further, a "reverse bias voltage" means a voltage of a direction reversely biasing the pn junction formed between a source or drain region and the semiconductor 5 substrate formed with a channel forming region or bulk region of the semiconductor layer.

Further, the "polarity giving a reverse bias to the channel forming region" means the plus polarity side or minus side direction of the supply of voltage based on 10 the potential of the channel forming region. Specifically, the direction when the conductivity type of the channel forming region is the p-type is the plus polarity side while the direction when it is the n-type is the minus polarity side.

15 The write inhibit voltage supply circuit 92 and the nonselected word line bias voltage 94 supply predetermined voltages to the gate electrodes 8 and the source regions 2 and drain regions 4 of the nonselected memory transistors before the programming of the selected 20 cell so as to prevent mistaken writing or mistaken erasure of the nonselected cells A and B of Fig. 1 and greatly improve the program disturbance margin.

Next, an explanation will be given of a write operation of a nonvolatile memory of this configuration.

25 Here, as shown in Fig. 1, the nonselected cells A to

C are defined by the connection relationship with the selected cell S. That is, the nonselected cell connected to the same selected word line WL1 as the selected cell S is defined as A, the nonselected cell connected to the 5 nonselected word line WL2 and connected to the same selected source line SL1 and selected bit line BL1 as the selected cell S is defined as C, and the nonselected cell connected to the selected word line WL2 and connected to the nonselected source line SL2 and nonselected bit line 10 BL2 is defined as B.

Figure 5 shows a first example of the conditions for setting the write bias voltage for these four types of cells.

When writing data in the selected cell S, first, the 15 nonselected word line bias circuit 94 is used to supply a predetermined voltage, for example, 2.5V, to the nonselected word line WL2 when the substrate potential is 0V. Further, the write inhibit voltage supply circuit 92 is used to supply a predetermined reverse bias voltage, 20 for example, 4V, to the nonselected source line SL2 and the nonselected bit line BL2 when the substrate potential is 0V. At this time, the selected source line SL1 and the selected bit line BL1 maintain the ground potential 0V.

In this state, a program voltage, for example, 7V, 25 is supplied to the word line WL1 to which the selected

cell S is connected. As a result, the potential of the gate electrode of the memory transistor M11 constituting the selected cell S rises to about 8V.

5 Figure 6 shows a second example of the conditions for setting the bias voltage.

In the second example of the conditions for setting the bias voltage, a negative voltage is supplied to the well to reduce the gate supply voltage while keeping the same electrical field applied to the gate insulating film
10 as the above case.

In the above Fig. 5, the well voltage was made 0V, but in Fig. 6, the voltage supplied to the well is made a negative voltage, for example, -3.5V. Therefore, it is possible to reduce the voltage supplied to the gate
15 electrode (selected word line WL1) from 7V to 3.5V. Note that along with the halving of the voltage supplied to the selected word line WL1, the voltage supplied to the selected bit line BL1 and the selected source line SL1 is reduced to -3.5V the same as the well, the voltage
20 supplied to the nonselected bit line BL2 and nonselected source line SL2 for prevention of disturbance is reduced to 0.5V, and the voltage supplied to the nonselected word line WL2 is reduced to -1.0V.

Due to the above, by supplying a negative voltage to
25 the well, it becomes possible to supply an operating

voltage at the time of a write operation from a polarity (plus/minus) power source with a low absolute voltage of 3.5V.

Figure 7 is a graph of a write/erase characteristic of a nonvolatile memory transistor in the case of using a silicon oxide film for the tunnel insulating film.

In Fig. 7, if the write end threshold voltage V_{th} is defined as 2V, the write time becomes 0.2 msec at a word line supply voltage 12V and about 20 msec at a word line supply voltage 10V. The write operation does not end even after 10 sec at a word line supply voltage of 7V.

In the write operation of the present embodiment, however, even if the word line potential is 7V, as explained above, the great reduction in the value, estimated (converted) to a silicon oxide film, of the gate insulating film 6 due to the use of an FN nitride film for the tunnel insulating film 10 differs from the case of Fig. 7. Therefore, in the write operation of this embodiment, the word line supply voltage 7V corresponds to a word line supply voltage of the related art of 11 to 11.5V if the tunnel electric field in the FN nitride film is made 10 to 12 MV/cm.

Therefore, in the write operation of the present embodiment, from Fig. 7, it is understood that a high speed write operation of 1 to 2 msec is realized at a

word line supply voltage of 7V. That is, a charge passes through the FN tunnel nitride film for FN tunneling to the charge storing means (carrier traps) of the memory transistor M11 of the selected cell S at a word line 5 supply voltage 7V from the entire surface of the channel forming region 1a of the semiconductor substrate 1. The threshold voltage V_{th} thereby changes and thus the data is written.

In this way, in the first embodiment, it is possible 10 to reduce the write voltage from the 11V to 12V of the related art to 7V while maintaining the same write speed.

In addition, due to similar reasons, in the first embodiment, it is possible to reduce the absolute value 15 of the word line supply voltage (erase voltage) enabling erasure of data from the related art at the same speed as in the related art. That is, it is possible to reduce the erase voltage from the -7V or so of the related art to -5V. In this case, in the first embodiment, since the gate insulating film is effectively thinner than the related 20 art, the erase speed is greatly improved even if supplying the same erase voltage.

In this write method, by supplying for example a positive voltage to the nonselected word line WL2, the disturbance margin of the nonselected cell B is increased 25 and therefore the nonselected cell B is not mistakenly

written or mistakenly erased.

Further, by supplying a reverse bias voltage to the nonselected bit line BL2 and the nonselected source line SL2, it is possible to prevent the nonselected cell A 5 from becoming written in by the supply of the program voltage of the selected word line WL1 and the nonselected cell B is not mistakenly written in (or mistakenly erased). If the order of supply of the bias voltage at this time is, as explained above, supply of voltage to 10 the nonselected word line, supply of reverse bias voltage, and supply of programming voltage, the nonselected cell B becomes resistant to disturbance.

Further, the reduction of the voltage supplied to the selected word line WL in the first embodiment from 15 for example 12V to 7V or so also has the effect of being advantageous in prevention of disturbance at the nonselected cells A and B.

The above explanation related to prevention of disturbance, but it is also necessary to investigate if 20 there is any problem in withstand voltage (junction withstand voltage) at the time of making the source and drain a reverse bias and confirm the main disturbance characteristic.

[Tolerance Voltage of Memory Transistor]

25 A study was made of the current-voltage

characteristic in the case of a gate voltage of 0V in both the cases of the write state and erase state.

As a result, it was understood that a yield voltage of the junction did not depend on the write state and
5 erase state. It was understood however that the rising voltage at the sub breakdown region near 3V to 5V differs in the write state and erase state.

A study was made of the dependency of the current-voltage characteristic on the gate voltage in the write
10 state. The yield voltage does not exhibit any dependency on the gate voltage, but the rising voltage at the sub breakdown region exhibits dependency on the gate voltage. The sub breakdown region is believed to be due to the interband tunnel phenomenon at the surface of the
15 drain/source region of the gate edge portion, but since the current level is small, it is believed to not be a problem here. Further, since even with a yield voltage of about 10V, the upper limit of the source-drain supply voltage (inhibit S/D voltage) is about 7V or giving a
20 sufficient margin, it is believed that there is no direct effect on the inhibit characteristic.

Due to the above, it was understood that in a 0.18 μm MONOS type memory transistor, the junction withstand (tolerance) voltage would not become a factor restricting
25 the program disturbance characteristic.

[Main Device Characteristic]

The current-voltage characteristic in the write state and erase state was studied.

When the gate voltage is 0V, the current of a
5 nonselected cell at a drain voltage of 1.5V is about 1
mA. Since the read current in this case is at least 10
 μ A, it is believed that no mistaken reading of a
nonselected cell will occur. Therefore, it was understood
that there was a sufficient margin of the punchthrough
10 tolerance (withstand) voltage at the time of a read
operation in a MONOS type memory transistor with a gate
length of 0.18 μ m. Further, the read disturbance
characteristic at a gate voltage of 1.5V was also
evaluated, but a read time of at least 3×10^8 sec
15 becomes possible.

The data write characteristic under write conditions
(program voltage= 7V, program time= 1 msec) and under
erase conditions (erase gate voltage= -5V, erase time= 100 msec) was studied. It was understood that the number
20 of data write life is a good 1×10^6 times since the
carrier traps are spatially dispersed. Further, the data
retention (charge holding) characteristics were 85°C and
10 years after 1×10^6 data rewrites.

Due to the above, it could be confirmed that a
25 sufficient characteristic was obtained as a 0.18 μ m

generation MONOS type nonvolatile memory transistor.

In the first embodiment, by using an FN tunnel nitride film for the tunnel insulating film, it is possible to provide the word line supply voltage (program voltage and erase voltage) at a voltage level greatly reduced from the related art and as a result possible to simplify the configuration of the operating voltage generating circuit.

Further, the FN tunnel nitride film is reduced in the leakage current accompanying the formation of defects (SILC) after data rewrites compared with an oxide film, so the repeatability of the write/erase operations, that is, the endurance characteristic, is improved. The endurance characteristic is already improved since the tunnel insulating film is relatively thick. The reason is that the injection of holes to the charge storing means is suppressed by the relatively thick tunnel insulating film and, as a result, the deterioration of the tunnel insulating film due to holes is suppressed.

Further, the data retention (charge holding) characteristics after data rewrites, the disturbance characteristic, and other facets of its reliability are improved.

In particular, in the first embodiment, the fact that by supplying for example a positive bias voltage to

06031073-A10490

a nonselected word line, it is possible to raise the upper limit of the inhibit S (source) /D (drain) voltage of the nonselected cell B connected to both a nonselected word line and a nonselected bit line and increase the 5 program disturbance margin could be experimentally confirmed in a 0.18 μm generation MONOS type nonvolatile memory. The dependency of this effect on the gate length was investigated. As a result, it was found the effect was particularly remarkable in a region with a gate 10 length shorter than 0.2 μm . The effect of improvement is due to the fact that in the case of the related art where the gate voltage is 0V, the channel forming region becomes depleted due to the reverse bias voltage, the field component increases in the direction draining the 15 held charge in the ONO film to the substrate side in the channel forming region of the transistor, and the gate voltage is reduced due to the application of a voltage biasing this in the reverse bias direction (positive direction in the first embodiment). It was understood that raising the upper limit of the inhibit S/D voltage 20 increases the program disturbance margin of the nonselected cell A connected to the same nonselected bit line. Further, the junction withstand voltage of the transistor was studied by experiments. As a result, it 25 was understood that the junction withstand voltage of the

transistor was larger than the inhibit S/D voltage and did not become a factor restricting the program inhibit characteristic. It was also confirmed that there was no effect on the main device characteristics. The data 5 showing the increase of the program disturbance margin can be applied due to its principle to a MONOS type memory transistor of the $0.18 \mu\text{m}$ generation and on as well.

Increasing the program disturbance margin

10 facilitates the realization of a single transistor cell, that is, a memory cell using a single transistor. To realize this, it is not only necessary to increase the disturbance margin, but also necessary to obtain an enhancement type memory cell which does not deplete the
15 threshold voltage of the memory transistor. By giving a greater margin to the program voltage, it is possible to increase the thickness of the tunnel film assuming the same program speed. Due to this, in the erase characteristics, the threshold voltage is hard to
20 deplete, a memory characteristic is obtained which is saturated at enhancement, and a single transistor cell becomes easier to realize in this respect as well.

In a single transistor cell, there is no need to provide a selected transistor for each memory cell, so the cell area is reduced and in turn the chip area is

卷之三

reduced resulting in reduced costs and larger capacity.

As a result, it becomes possible to realize, at a low cost, a large capacity MONOS type nonvolatile memory with a cell area equal to that of a NOR type, AND type, NAND

5 type, DINOR type, or other FG type nonvolatile memory.

Note that the write inhibit voltage supply circuit in this example can be used for effective enhancement operation by reading information in a state with the source region reversely biased.

10 Due to the above, in the first embodiment, it becomes possible to easily realize a single transistor cell operating with a low voltage.

Second Embodiment

Figure 8 is a view of the general configuration of a 15 nonvolatile semiconductor memory according to a second embodiment of the present invention.

The nonvolatile memory device 100 of the second embodiment is the same as that of the first embodiment in that each memory cell is comprised of a divided source line NOR type single transistor cell and that suitable use can be made of a fine NOR type memory cell array pattern with meandering source lines (Fig. 2) and in the connection relationship of the word lines, bit lines, and divided source lines to the memory cells.

25 In the second embodiment, while details will be

explained later, a pull-up electrode is provided through a dielectric film on the gate electrode of each memory transistor.

5 The pull-up electrodes of the memory transistors are for example connected in common to pull-up lines arranged in the word direction.

10 The pull-up electrodes of the memory transistors M11 and M21 adjoining each other in the word direction are connected to a pull-up line PL1. Similarly, the pull-up electrodes of the memory transistors M12 and M22 adjoining each other in the word direction are connected to a pull-up line PL2.

15 The pull-up lines PL1, PL2,... have a pull-up gate bias circuit 102 connected to them through a common selected transistor ST0. The pull-up gate bias circuit 102 is a circuit for raising a word line to a predetermined potential at the time of a write operation. Due to this, it is possible to reduce the write voltage supplied in advance to the word line selected at the time 20 of the write operation (hereinafter also referred to as the program voltage or precharge voltage).

Under this control, it is necessary to make the word line float in potential after supply of the program voltage. Therefore, the word lines WL1, WL2,... are 25 connected to a not shown word line selection circuit (row

decoder) through the selected transistors ST1, ST2,...

Figure 9 is a sectional view of the element structure of a MONOS type memory transistor according to the second embodiment.

5 The MONOS type nonvolatile memory transistor of the second embodiment is, like the first embodiment, provided with a semiconductor substrate 1, a source region 2, a drain region 4, a gate insulating film 6 comprising a tunnel insulating film (FN tunnel nitride film) 10, a nitride film 12 and a top insulating film 14, a channel forming region 1a, and a gate electrode 8.

10

In the second embodiment, a pull-up electrode 18 is stacked on the gate electrode 8 through a dielectric film 16.

15 The dielectric film 16 is comprised of a high temperature chemical vapor deposited oxide (HTO) film or CVD-SiO₂ film. The thickness is for example about 10 nm.

A pull-up electrode 18 is generally comprised of doped poly-Si or a stacked film of a doped poly-Si and a 20 high melting point metal silicide.

The process of production of this nonvolatile memory transistor is the same as that of the first embodiment up to the formation of the top insulating film 14.

25 In the second embodiment, next, a dielectric film 16 is formed on the top insulating film 14 by HT-CVD or LP-

CVD, then a film forming the pull-up electrode 18 is formed by LP-CVD - each to the predetermined thickness.

The dielectric film 16 and the film forming the pull-up electrode 18 are then continuously etched by for 5 example RIE along with the underlying top insulating film 14, nitride film 12, and FN tunnel nitride film 10.

This ends the patterning of the gate electrode and the pull-up electrode. Next, the same steps as in the 10 first embodiment are gone through to complete the nonvolatile memory transistor.

Next, an explanation will be made of the write operation.

Figure 10 is a view of showing the conditions for 15 setting the write bias voltage of the second embodiment for four types of cells defined in the same way as the first embodiment.

When writing data in the selected cell S, first, the selected bit line BL1 and selected source line SL1 are held at a low level voltage, for example, a ground potential 0V, then a high level voltage, for example, 4V, 20 is set to the other nonselected bit line BL2 and source line SL2. Further, when the substrate potential is 0V, a predetermined voltage, for example, 2.5V, is supplied to the nonselected word line WL2.

25 In this state, a voltage of not more than 10V, for

example, 5V, is supplied to the word line WL1 to which the selected cell S is connected through the selected transistor ST1 so as to precharge the selected word line WL1. Therefore, the potential of the gate electrode of 5 the memory transistor M11 constituting the selected cell S is raised to about 5V, but sufficient writing is not performed at that potential.

Next, the selected transistor ST1 connected to the selected word line WL1 is turned off and the selected 10 word line WL1 electrically floats in state.

Further, next, the selected transistor ST0 to which the pull-up line is connected is turned on and the pull-up gate bias circuit 102 supplies the pull-up line PL1 to which the selected cell S is connected with a 15 predetermined voltage of not more than 10V, for example, 5V.

Due to this, the selected word line WL1 is raised to a writable voltage. The final word line potential V_w after boosting is expressed by the following equation 1:

20
$$V_w = V_{pc} + C \times V_{pull} \quad (1)$$

where, V_{pc} is the precharge voltage of the word line,

C is the capacity coupling ratio of the pull-up electrode and word line, and

25 V_{pull} is the voltage supplied to the pull-up

electrode (pull-up voltage).

In the above example, both the precharge voltage V_{PC} and the pull-up voltage V_{PULL} are 5V. Here, if the capacity coupling ratio is 0.6, from equation (1), the 5 word line potential V_W after boosting becomes 8V. This word line potential V_W of 8V corresponds to a word line supply voltage of 11 to 11.5V in the case where the tunnel insulating film is comprised of silicon oxide like in the first embodiment (Fig. 7).

10 As a result, the charge passes through the FN tunnel nitride film 10 for FN tunneling to the charge storing means (carrier traps) of the memory transistor M11 of the selected cell S from the entire surface of the channel forming region 1a of the semiconductor substrate 1. The 15 threshold voltage V_{TH} thereby changes and the data is written.

In this way, in the write operation of the second embodiment, a high speed write operation of 1 msec is achieved by a word line supply voltage 5V (word line potential of 8V after boosting).

Further, for the same reasons, erasing is possible by an erase voltage of -5V at the same speed (100 msec) as with an erase voltage of -7V of the related art.

25 Due to the above, it is possible to provide the operating voltage at a greatly reduced voltage level from

00000000000000000000000000000000

the word line supply voltage, that is, 5V at the time of a write operation and -5V at the time of an erase operation. As a result, it is possible to extremely simplify the configuration of the not shown operating 5 voltage generating circuit and further possible to achieve a reduction of the chip area and a reduction of the power consumption.

Note that in the second embodiment as well, in the same way as the first embodiment, it is possible to 10 supply a negative voltage to the well in order to further reduce the voltage.

Further, in the second embodiment as well, in the same way as the first embodiment, the reducing action of the FN tunnel nitride film improves the endurance 15 characteristic. Further, since the tunnel insulating film is relatively thick, the data retention (charge holding) characteristics after data rewrites, the disturbance characteristic, and other facets of its reliability are improved.

20 Third Embodiment

The third embodiment relates to a nonvolatile semiconductor memory having miniature NOR type cells with bit lines and source lines formed in a hierarchy structure.

25 Figure 11 is a view of the general configuration of

6570774 9/07/960

a nonvolatile semiconductor memory according to the third embodiment.

In the nonvolatile memory device 110 of the third embodiment, the bit lines are divided into main bit lines 5 and sub bit lines while the source lines are divided into main source lines and sub source lines. The sub bit line SBL1 is connected to the main bit line MBL1 through the selected transistor S11, while the sub bit line SBL2 is connected to the main bit line MBL2 through the selected 10 transistor S21. Further, the sub source line SSL1 is connected to the main source line MSL through the selected transistor S12, while the sub source line SSL2 is connected through the selected transistor S22.

The memory transistors M11 to M1n are connected in 15 parallel between the sub bit line SBL1 and the sub source line SSL1, while the memory transistors M21 to M2n are connected in parallel between the sub bit line SBL2 and the sub source line SSL2. The n number of memory transistors connected in parallel to each other and the 20 two selector transistors (S11 and S12 or S21 and S22) constitute a unit block constituting the memory array.

The gates of the memory transistors M11, M21,... adjoining each other in the word direction are connected to the word line WL1. Similarly, the gates of the memory 25 transistors M12, M22,... are connected to the word line

WL2 and the gates of the memory transistors M1n, M2n, ... are connected to the word line WL_n.

The selected transistors S11, S21,... adjoining each other in the word direction are controlled by the selection line SG1, while the selected transistors S12, S22,... are controlled by the selection line SG2.

The memory transistors have the structure shown in Fig. 9 for example. A pull-up electrode is provided on the gate electrode through a dielectric film. In the same way as the second embodiment, the pull-up electrodes of the memory transistors are connected in common to the pull-up lines arranged in the word direction. Specifically, the pull-up electrodes of the memory transistors M11 and M21 are connected to the pull-up line PL1, the pull-up electrodes of the memory transistors M12 and M22 are connected to the pull-up line PL2, and the pull-up electrodes of the memory transistors M1n and M2n are connected to the pull-up line PLn.

In the same way as the second embodiment, the pull-up gate bias circuit 102 is connected to the pull-up lines PL1, PL2, ..., PLn through the selected transistor ST0.

In the third embodiment as well, in the same way as the first and second embodiments, by using an FN tunnel nitride film for the tunnel insulating film, it is

possible to provide the word line supply voltage (program voltage and erase voltage) by a voltage level greatly reduced from the related art. As a result, it is possible to simplify the configuration of the operating voltage

5 generating circuit. In the same way as the first embodiment, it is possible to reduce the voltage further by supply of a negative voltage to the well and to improve the enhancement characteristic and the reliability after data rewrites.

10 In the third embodiment, since the bit lines and the source lines are formed in a hierarchy structure and the selected transistor S11 or S21 separates the group of parallel main transistors in the nonselected unit blocks from the main bit line MBL1 or MBL2, the capacitance of

15 the main bit lines is remarkably reduced which is advantageous for increasing the speed and lowering the power consumption. Further, due to the action of the selected transistor S12 or S22, it is possible to separate the sub source lines from the main source lines

20 and thereby reduce the capacity.

In addition, it is possible to form a pseudo contact-less structure where the sub lines (sub bit lines and sub source lines) are made by impurity regions and possible to reduce the effective cell area per bit from

25 the NOR type cell shown in the second embodiment.

For example, by using trench separation, self-aligned fabrication, for example, self-aligned contact formation using miniature NOR type cells shown in Fig. 2, etc., it is possible to produce miniature cells with 5 exclusive areas of $6F^2$, where F is the minimum design rule. At the time of production, the sub bit lines SBL1 and SBL2 or the sub source lines SSL1 and SSL2 are formed by the impurity regions or impurity regions bonded with a silicide, while the main bit lines MBL1 and MBL2 used may 10 be metal lines.

Further, it is possible to use full channel surface write and full channel erase operations.

If using full channel write/erase operations, it is not necessary to use a double diffusion layer structure 15 for suppressing the interband tunnel current in the drain or source impurity regions, so this is superior in terms of the scaling of the source and drain impurity regions of the memory transistors compared with the operation of draining the stored charges to the impurity regions. As a 20 result, it is possible to realize a memory transistor superior in the fine scaling of the cells and therefore having a finer gate length.

Fourth Embodiment

Figure 12 is a view of the general configuration of 25 a nonvolatile semiconductor memory according to a fourth

embodiment of the present invention.

The nonvolatile semiconductor memory 120 of the fourth embodiment is the same as the second embodiment in the configuration of the memory cell array, the structure 5 of the memory transistors, and the process of production.

The configuration for boosting the voltage of the gate electrodes of the memory transistors in the fourth embodiment is similar to those of the second and third embodiments in that, as shown in Fig. 12, a pull-up 10 electrode is provided in the memory transistor, the pull-up lines PL1 and PL2 are connected to the pull-up electrodes, and the pull-up gate bias circuit 102 is connected to the pull-up lines PL1 and PL2 through the selected transistor ST0.

15 Further, the write and erase methods are basically similar to those of the second embodiment.

However, the difference of the fourth embodiment in configuration from that of the second embodiment is that provision is made of the write inhibit voltage supply 20 circuit 92 and the nonselected word line bias circuit 94 as the specific means for supplying the voltage of 4V for the nonselected bit line BL2 and nonselected source line SL2 of Fig. 10 and supplying the voltage of 2.5V for the nonselected word line WL2 in the same way as the first 25 embodiment.

Table 1 shows the characteristics of the nonvolatile semiconductor memory 120 according to the fourth embodiment.

Table 1

5	Program condition	5V, 1 msec
	Erase condition	-5V, 100 msec
	W/E write life	to 10^6 cycle
	Data retention condition	85°C, 10 years (after 100,000 rewrites)
	Read disturbance time	10 years (after 100,000 rewrites)
10	Inhibit S/D voltage	4V
	Junction withstand voltage	10V

15 In the fourth embodiment, the same program conditions (5V, 1 msec) and erase conditions (-5V, 100 msec) are achieved as in the second embodiment.

Further, it was confirmed that the data write life was 1×10^6 times, the data retention (charge holding) characteristics were 85° and 10 years after 1 million rewrites, and the read disturbance was one where 10 years 5 could be guaranteed after 1 million rewrites. These measurements were made at an inhibit S/D voltage of 4V.

Further, the main device characteristics were good and the junction withstand (tolerance) voltage of the memory transistor satisfied the 10V requirement.

10 In the fourth embodiment as well, in the same way as the second embodiment, it was possible to use an FN tunnel nitride film for the tunnel insulating film and to boost the word line voltage to provide a word line supply voltage (program voltage and erase voltage) at a voltage 15 level (for example, 5V) greatly reduced from the related art and as a result possible to simplify the configuration of the operating voltage generating circuit.

The fourth embodiment, like the first embodiment, 20 improves the endurance characteristic and the reliability after data rewrites by increasing the disturbance margin, facilitates the realization of a single transistor cells operating at a low voltage, and as a result enables a reduction of the cell area and in turn a reduction in the 25 chip area and thereby a reduction in the costs and an

increase in the capacity.

Fifth Embodiment

The fifth embodiment is a first modification of the element structure of a nonvolatile memory.

5 Figure 13 is a sectional view of the element structure of a memory transistor of the fifth embodiment.

The nonvolatile memory transistor of the fifth embodiment differs from that of the second embodiment in that the gate insulating film 20 of the fifth embodiment 10 is provided with an oxynitride film 22 in place of the nitride film 12.

The rest of the configuration, that is, the semiconductor substrate 1, source region 2, drain region 4, channel forming region 1a, tunnel insulating film 10, 15 top insulating film 14, gate electrode 8, dielectric film 16, and pull-up electrode 18, are similar to these of the second embodiment. The oxynitride film 22 can be made a relatively thin 3.0 nm for example since an FN tunnel nitride film is used for the tunnel insulating film 10 in 20 the same way as the first and second embodiments.

In the production of a memory transistor of this configuration, after the formation of the tunnel insulating film 10, the oxynitride film 22 is deposited thickly by for example LP-CVD to give a final thickness 25 of 3.0 nm. The CVD is performed using a mixed gas for

601077-9/07/060

example of DCS, ammonia, and N₂O and at a substrate temperature of 650°C. In the formation of an oxynitride film over the heat oxidized film (SiO_xN_y film; 0<x<1, 0<y<1), if necessary, it is possible to optimize the 5 pretreatment (wafer pretreatment) and film forming conditions of the underlying surface in advance in the same way as the first embodiment. Next, in the same way as the first and second embodiments, the top insulating film 14, the gate electrode 8, the dielectric film 16, 10 and the pull-up electrode 18 are formed and processed to complete the MONOS type memory transistor.

In the fifth embodiment too, like the first and second embodiments, good characteristics are obtained as a single transistor cell able to operating at a low 15 voltage.

The fifth embodiment, like the second embodiment, gives the effect by pulling up the potential of the gate electrode.

Sixth Embodiment

20 The sixth embodiment is a second modification of the element structure of a nonvolatile memory.

Figure 14 is a sectional view of the element structure of a memory transistor of the sixth embodiment.

25 The nonvolatile memory transistor of the sixth embodiment differs from that of the second embodiment in

that the gate insulating film 23 of the sixth embodiment provides a buffer layer 24 between the FN tunnel nitride film 10 and the substrate 1. The buffer layer 24 is a thin PF film formed by heat nitridation of the substrate 5 surface and acts to suppress the generation of the interfacial level at the substrate surface.

The rest of the configuration, that is, the semiconductor substrate 1, source region 2, drain region 4, channel forming region 1a, tunnel insulating film 10, 10 nitride film 12, top insulating film 14, gate electrode 8, dielectric film 16, and pull-up electrode 18, are similar to those of the second embodiment. The nitride film 12 can be made a relatively thin 3.0 nm for example since an FN tunnel nitride film is used for the tunnel 15 insulating film 10 in the same way as the first and second embodiments.

The memory transistor of this configuration is produced in the same way as the first and second embodiments except for the heat nitridation of the 20 substrate surface at the start of the formation of the gate insulating film.

In the sixth embodiment too, like the first and second embodiments, good characteristics are obtained as a single transistor cell able to operating at a low 25 voltage.

The sixth embodiment, like the first and second embodiments, gives the effect by pulling up the potential of the gate electrode.

In particular, in the sixth embodiment, since the boundary (interfacial) energy level of the substrate surface is suppressed and the probability of the carriers being trapped there is reduced, the amount of charge held becomes greater and the characteristics are improved. Further, the buffer layer 24 eases the strain on the FN tunnel nitride film 10 and therefore there is no increase in the number of carrier traps of the FN tunnel nitride film 10 due to the strain.

Seventh Embodiment

The seventh embodiment is a third modification of
15 the element structure of a nonvolatile memory.

Figure 15 is a sectional view of the element structure of a memory transistor of the seventh embodiment.

The nonvolatile memory transistor of the seventh embodiment differs from that of the first to sixth embodiments in that the gate insulating film 25 of the seventh embodiment omits the nitride film 12 (or oxynitride film 22) deposited by LP-CVD and exhibiting a PF electroconductivity and enables the top insulating film 14 to be directly formed on the FN tunnel nitride

卷之三

film 10.

The FN tunnel nitride film 10 has a relatively low density of carrier traps in the film compared with a PF film, so the carrier traps formed at the boundary 5 (interface) with top insulating film 14 are mainly responsible for holding the charges. The seventh embodiment shows that it is possible to make the thickness of the PF film, which had to be reduced to a thickness of about 3 nm in the previous embodiments, to 10 0, that is to omit it, when there are sufficient carrier traps for holding the charges.

To keep down the reduction in the number of carrier traps for holding a charge due to the film stress as much as possible, it is desirable to provide a buffer layer 24 15 at the bottommost layer of the gate insulating film in the same way as in the sixth embodiment.

The rest of the configuration, that is, the semiconductor substrate 1, source region 2, drain region 4, channel forming region 1a, tunnel insulating film 10, 20 top insulating film 14, gate electrode 8, dielectric film 16, and pull-up electrode 18, are similar to those of the first to sixth embodiments.

The memory transistor of this configuration is produced in the same way as the first to sixth 25 embodiments except for omitting the PF film (nitride film

12 or oxynitride film 22).

In the seventh embodiment, it is possible to further reduce the operating voltage from the first to sixth embodiments by just omitting the PF film (nitride film 12 or oxynitride film 22).

The seventh embodiment, like the second embodiment, gives the effect by pulling up the potential of the gate electrode.

Further, when providing the buffer layer 24, the boundary (interfacial) energy level of the substrate surface is suppressed and the probability of the carriers being trapped is reduced.

Eighth Embodiment

The eighth embodiment is a fourth modification of the element structure of a nonvolatile memory.

Figure 16 is a sectional view of the element structure of a memory transistor of the eighth embodiment.

The nonvolatile memory transistor of the eighth embodiment differs from that of the previous second embodiment in that the gate insulating film 26 of the eighth embodiment provides a buffer layer 27 between the FN tunnel nitride film 10 and the PF film (nitride film 12). The buffer layer 27 acts to prevent the effect from the upper layer nitride film 12 side due to heating etc.

660077-970760

after formation of the FN tunnel nitride film 10, for example, the change in quality near the interface with the nitride film 12 and the effective reduction in the thickness of the FN tunnel nitride film 10.

5 The rest of the configuration, that is, the semiconductor substrate 1, source region 2, drain region 4, channel forming region 1a, tunnel insulating film 10, nitride film 12, top insulating film 14, gate electrode 8, dielectric film 16, and pull-up electrode 18, are
10 similar to those of the first and second embodiments. The nitride film 12 can be made a relatively thin 3.0 nm for example since an FN tunnel nitride film is used for the tunnel insulating film 10 in the same way as the first and second embodiments.

15 The memory transistor of this configuration is produced in the same way as the first and second embodiments except for the formation of the nitride film 12 after formation of the buffer layer 27 by the above method after formation of the FN tunnel nitride film 10.

20 In the eighth embodiment too, like the first and second embodiments, good characteristics are obtained as a single transistor cell able to operating at a low voltage.

25 The eighth embodiment, like the second embodiment, gives the effect by pulling up the potential of the gate

electrode.

In particular, in the eighth embodiment, there is the advantage of the buffer layer 27 effectively preventing the upper layer film from affecting the FN tunnel nitride film 10 and keeping the quality, thickness, etc. of the FN tunnel nitride film 10 from changing in the middle of production.

Ninth Embodiment

The ninth embodiment relates to a nonvolatile 10 semiconductor memory device using as charge storing means of the memory transistor a large number of mutually insulated Si nanocrystals having a particle size of for example not more than 10 nanometers buried in the gate insulating film (hereinafter referred to as the Si 15 nanocrystal type).

Figure 17 is a sectional view of the element structure of an Si nanocrystal type memory transistor of the ninth embodiment.

The Si nanocrystal nonvolatile memory transistor of 20 the ninth embodiment differs from that of the first to eighth embodiment in that instead of the nitride film 12 and the top insulating film 14, it forms the Si nanocrystals 32 forming the charge storing means on the tunnel insulating film 10 and the oxide film 34 over it 25 with the gate electrode 8.

6640774-9/20/2020

The rest of the configuration, that is, the semiconductor substrate 1, channel forming region 1a, source region 2, drain region 4, tunnel insulating film 10, gate electrode 8, dielectric film 16, and pull-up electrode 18, are similar to those of the previous embodiments.

The Si nanocrystals 32 have a size (diameter) of preferably not more than 10 nm, for example, about 4.0 nm. The individual Si nanocrystals are separated 10 spatially at the oxide film 34 at intervals of for example 4 nm or so.

The tunnel insulating film 10 at the ninth embodiment is somewhat thicker than the first embodiment due to the closeness of the charge storing means (Si 15 nanocrystals 32) to the substrate side. The thickness may be suitably selected in the range from 2.6 nm to 5.0 nm in accordance with the application of the nonvolatile semiconductor memory. Here, it is made a thickness of about 4.0 nm.

20 The memory transistor of this configuration is produced by forming the tunnel insulating film 10, then forming a plurality of Si nanocrystals 42 on the tunnel insulating film 10 by for example LP-CVD. Further, the oxide film 44 is formed by for example LP-CVD to for 25 example 7 nm in a form burying the Si nanocrystals 42. In

664077-9/207660

this LP-CVD, the material gas is a mixed gas of DCS and N₂O and the substrate temperature is for example 700°C. At this time, the Si nanocrystals 32 are buried in the oxide film 34 and the surface of the oxide film 34 5 planarized. When the planarization is insufficient, a new planarization process (for example, CMP etc.) may be performed. Next, the films forming the gate electrode 8, dielectric film 16, and pull-up electrode 18 are formed and processed to complete the Si nanocrystal type memory 10 transistor.

The Si nanocrystals 32 formed in this way function as carrier traps dispersed in the planar direction. The trap level can be deduced by the band discontinuity with the surrounding silicon oxide. It is deduced to be about 15 3.1 eV or so. Individual Si nanocrystals 32 of this size can hold several electrons. Note that the Si nanocrystals can also be made smaller and made to hold single electrons.

The data retention (charge holding) characteristics 20 of an Si nanocrystal type nonvolatile memory of this configuration was studied by a land cast back tunneling model. To improve the data retention (charge holding) characteristics, it is important to make the trap level deep and increase the distance between the center of the 25 charge and the semiconductor substrate 1. Therefore, the

data retention (charge holding) characteristics in the case of a trap level of 3.1 eV was studied by simulation using a land cast model as a physical model. As a result, it was understood that by using deep carrier traps of a 5 trap level of 3.1 eV, a good data retention (charge holding) characteristics is exhibited even with a relatively close distance from the charge accumulating (storing) medium to the channel forming region 1a of 4.0 nm. Results were obtained as expected.

10 Next, low voltage programming was studied. The write time in the ninth embodiment is not more than 1 msec at a program voltage of a low 3V due to the effective action of the boosting effect of the word line by the pull-up electrode. The high speed write characteristic of the Si 15 nanocrystal type was therefore verified.

10th Embodiment

The 10th embodiment relates to a nonvolatile semiconductor device using a large number of fine divided type floating gates

20 Figure 18 is a sectional view of the element structure of a fine divided FG type memory transistor of the 10th embodiment.

The fine divided FG type nonvolatile memory of the 10th embodiment differs from the first to ninth 25 embodiments in the formation of the memory transistors on

a semiconductor-on-insulator (SOI) substrate, in the formation of the gate insulating film 40 of the 10th embodiment in place of the nitride film 12 and the top insulating film 14, and in the formation of the fine 5 divided type floating gate 42 and oxide film 44 over that forming the charge storing means on the tunnel insulating film 10 with the gate electrode 8.

In the rest of the configuration, the tunnel insulating film 10, gate electrode 8, dielectric film 16, and pull-up electrode 18 are the same as in the first to ninth embodiments.

The fine divided floating gate 42 corresponds to a specific example of the Si nanocrystal of the fifth embodiment and "small particle size conductors" spoken of in the present invention.

As the SOI substrate, use may be made of a separation-by-implanted-oxygen (SIMOX) substrate comprised of a silicon substrate doped with oxygen ions at a high concentration to form a buried oxide film at a 20 location deeper than the substrate surface, a bonded substrate comprised of one silicon substrate formed with an oxide film on its surface bonded with another substrate, etc. The SOI substrate formed by this method and shown in Fig. 12 is comprised of a substrate 46, a 25 divided oxide film 48, and a silicon layer 50. A channel

forming region 50a, source region 2, and drain region 4 are provided in the silicon layer 50.

Here, as the substrate 46, use may be made of not only a semiconductor substrate, but also a glass 5 substrate, plastic substrate, sapphire substrate, and other substrates other than semiconductor substrates.

The fine divided floating gate 42 comprises a normal FG type floating gate processed into fine poly-Si dots of a height of for example 5.0 nm or so and a diameter of up 10 to 8 nm.

The tunnel insulating film 10 in the 10th embodiment is somewhat thicker than that of the first embodiment, but is formed much thinner than the normal FG type. The thickness may be suitably selected from a range of 2.5 nm 15 to 4.0 nm in accordance with the application of the nonvolatile semiconductor memory. Here, it is made the thickest 4.0 nm.

In the production of the memory transistor of this configuration, a tunnel insulating film 10 is formed on 20 the SOI substrate, then for example a polycrystalline silicon film (final thickness: 5 nm) is formed on the tunnel insulating film 10. In LP-CVD, the material gas is made a mixed gas of DCS and ammonia and the substrate temperature is made for example 650°C. Next, for example, 25 electron beam exposure is used to process the

polycrystalline silicon film into fine poly-Si dots of a diameter of for example up to 8 nm. The poly-Si dots function as a fine divided type floating gate 42 (charge storing means). Next, an oxide film 44 is formed to a 5 thickness of for example up to 9 nm by LP-CVD in a form burying the fine divided type floating gate 42. In the LP-CVD, the material gas is made a mixed gas of DCS and N₂O and the substrate temperature is made for example 700°C. At this time, the fine divided type floating gate 10 42 is buried in the oxide film 44 and the surface of the oxide film 44 is planarized. When the planarization is insufficient, a new planarization process (for example, CMP etc.) may be performed. Next, the films forming the gate electrode 8, dielectric film 16, and pull-up 15 electrode 18 are formed and processed to complete the fine divided FG type memory transistor.

In this way, an SOI substrate was used and the floating gate finely divided. An element was produced and the characteristics evaluated. As a result, it was 20 confirmed that good characteristics were obtained as predicted.

Modifications

Various modifications may be made in the first to 10th embodiments explained above.

25 For example, the tunnel insulating film 10 is not

limited to an FN tunnel nitride film. It may also be configured by an oxynitride film, aluminum oxide film, tantalum pentaoxide film, or BST film exhibiting an FN tunneling electroconductivity.

5 Further, the other film exhibiting a PF electroconductivity may be comprised of any of a nitride film, oxynitride film, aluminum oxide film, or tantalum pentaoxide film.

10 For example, in the above explanation, the top insulating film 14 was made a single oxide film, but it is also possible to make the top insulating film 14 a plurality of stacked films.

15 For example, the top insulating film 14 may be comprised of a bottom layer of an oxide film and a top layer of an FN tunnel nitride film. Due to this, it is possible to further reduce the thickness of the ONO film converted to that of a silicon oxide film and as a result to further reduce the operating voltage.

20 Further, it is possible to comprise the top insulating film 14 from a bottom layer of a heat oxide film and a top layer of a CVD oxide film. Due to this, when reducing the thickness of the intermediate nitride film of the ONO film, it is possible to suppress the faster oxidation when forming the top insulating film by 25 heat oxidation of the nitride film and further possible

to reduce the total amount of high temperature heating,
that is, the thermal budget.

The pull-up lines PL1, PL2,... in the second to 10th
embodiments are connected through the selected
5 transistors with different pull-up lines to the pull-up
gate bias circuit 102. The pull-up lines PL1, PL2, ...
may be individually controlled by the pull-up gate bias
circuit 102.

The cell pattern is not limited to Fig. 2. Further,
10 the element structure is not limited to Fig. 3, Fig. 9,
and Fig. 13 to Fig. 19.

For example, the pull-up electrode 18 may be
arranged close to the gate electrode 8 through the
dielectric film 16. The pattern need not be the same as
15 the gate electrode 8. To raise the capacity coupling
ratio of the electrodes 8 and 18, it is preferable that
the pull-up electrode 18 cover the top surface and side
surfaces of the gate electrode 8. Further, it is also
possible to not divide the pull-up electrode 18, but for
20 example to form it into a plate for each area comprised
of units of a predetermined number of blocks.

Further, the source region 2 and drain region 4 may
be formed, without doping impurities, by inducing a
reversal layer in accordance with the voltage supplied to
25 the nearby electrode through the insulating film. In this

case, the source line and bit line are capacity coupled with the source region 2 and the drain region 4.

The "planarily dispersed charge storing means" in the present invention means carrier traps of the nitride film bulk, carrier traps formed near the interface between the oxide film and nitride film, nanocrystals of silicon etc. of a particle size of for example not more than 10 nm mutually insulated from each other, a fine divided floating gate of polycrystalline silicon etc.

5 divided into fine dots, etc.

10

Therefore, in addition to the above embodiments, it is possible to apply the present invention even to an MNOS type where the basic film structure of the gate insulating film is comprised of two layers of a nitride film and FN tunnel film. Note that as the FN tunnel film in this case, a material which enables sufficient formation of carrier traps near the interface with the nitride film and has a larger dielectric constant than silicon oxide is selected.

15

20 The explanation of the first embodiment assumed that the write inhibit voltage supply circuit 92 gave the same reverse bias voltage simultaneously to both of the source region 2 and the drain region 4 of a memory transistor, but the present invention is not limited to the same reverse bias voltage. Further, it is possible to give a

25

reverse bias voltage to one of the source region 2 and drain region 4 and leave the other open. Further, it is possible to supply different voltages to the source line and bit line.

5 Looking at the fine cell structure with the bit lines or source lines separated into different classes, the present invention may be applied to not only the configuration of Fig. 7 known as the so-called AND type but also for example the DINOR type and a fine NOR type
10 cell known as a so-called HiCR type comprised of a divided source line type memory cell array where source lines are shared by two adjoining source regions.

Further, it is possible to apply the present invention even to a so-called NAN type cell structure. In
15 that case, while not particularly shown, a number of memory transistors M11 to M1n or M21 to M2n connected in parallel in each unit block in Fig. 11 are connected in series between the selected transistors S11 and S12 or the selected transistors S21 and S22.

20 The present invention was explained with reference to a one-transistor memory cell, that is, a memory cell using a single transistor, but making the tunnel insulating film an FN tunnel nitride film or boosting the gate electrode by capacity coupling with a pull-up
25 electrode so as to reduce the operating voltage is

00000000000000000000000000000000

effective even for a two-transistor memory cell providing each memory cell with a selected transistor controlling the connection with common lines of the memory transistors.

5 Further, the present invention can also be applied to an enhancement type nonvolatile memory provided with logic circuits on the same substrate in addition to a stand alone type nonvolatile memory.

10 Note that the embodiments may be combined in any way. Further, use of an SOI substrate as in the 10th embodiment can be applied additionally over the memory transistor structure of the first to ninth embodiments.

15 Summarizing the effect of the invention, according to the nonvolatile semiconductor memory device, process of production, and write method of the present invention, it is possible to reduce the effective thickness of the gate insulating film and reduce the operating voltage.

20 Further, it is possible to boost the gate electrode (or word line) of the memory transistor precharged by the write voltage by the voltage supplied to the pull-up electrode. Therefore, it is possible to further reduce the write voltage without reducing the write speed and possible to correct the asymmetry of the write voltage and erase voltage.

25 Further, the program disturbance margin of the

000134075-20200606

nonselected memory transistor is increased and as a result realization of a one-transistor memory cell operating at a low voltage becomes easy.

660011-920760

What is claimed is:

1. A nonvolatile semiconductor memory device comprising a plurality of memory elements formed in the vicinity of the surface of a substrate, a plurality of word lines for driving the memory elements, and a plurality of bit lines,
 - 5 each of said plurality of memory elements including:
 - a semiconductor channel forming region formed
 - 10 in the vicinity of the surface of the substrate, a source region in contact with the channel forming region in the vicinity of the surface of the substrate,
 - 15 a drain region in contact with the channel forming region at a position facing the source region in the vicinity of the surface of the substrate,
 - 20 a gate insulating film including a tunnel insulating film formed on the channel forming region, a conductive gate electrode formed on the gate insulating film, and
 - 25 a charge storing means which is provided in the tunnel insulating film and in the gate insulating film and is planarly dispersed to the other neighbor charge storing means in the gate insulating film;

650077-920760

25 a gate electrode of the plurality of memory

elements being respectively connected to the plurality of word lines;

5 a gate insulating film formed on the semiconductor channel forming region and comprising a Fowler-Nordheim (FN) type tunneling film which has a FN type tunneling electroconductivity and contains material having a dielectric constant greater than that of silicon oxide;

10 a gate electrode formed on the gate insulating film; and

a charge storing means, formed in the gate insulating film, and facing to the surface of the channel forming region.

2. A nonvolatile semiconductor memory device
15 according to claim 1, wherein the FN tunneling film comprises any one of a nitride film, an oxynitride film, and aluminum oxide film, a tantalum pentaoxide film and a BST (BaSrTiO₃) film, having an FN tunneling electroconductivity.

20 3. A nonvolatile semiconductor memory device according to claim 1, wherein the gate insulating film includes a buffer layer formed between the FN tunneling film and the channel forming region and suppressing an interface trap level.

25 4. A nonvolatile semiconductor memory device

according to claim 1, wherein the gate insulating film comprises a Pool-Frenkel (PF) type film including any one of a nitride film, an oxynitride film, and aluminum oxide film, a tantalum pentaoxide film and a BST (BaSrTiO₃) film, having an PN type electroconductivity.

5. A nonvolatile semiconductor memory device according to claim 4, wherein the gate insulating film includes a buffer layer formed between the FN tunneling film and the PN film.

10 6. A nonvolatile semiconductor memory device according to claim 1, further comprising:

a pull-up electrode in the vicinity of the gate electrode or a wiring layer connected to the gate electrode, via a dielectric film; and

15 7. A pull-up gate bias means for applying a voltage to the pull-up electrode.

7. A nonvolatile semiconductor memory device according to claim 6, wherein a plurality of gate electrode of the plurality of memory transistors are connected to a plurality of word lines, and

20 a selected transistor is connected between the pull-up gate bias means and the pull-up electrode, said pull-up gate bias means supplying a voltage having a polarity same to a polarity of a boosting voltage for

boosting the precharged word line by a capacitance coupling.

8. A nonvolatile semiconductor memory device according to claim 6, wherein the pull-up electrode is 5 arranged in the vicinity of an upper portion of the gate electrode or a connection layer connected to the gate electrode, via the dielectric film.

9. A nonvolatile semiconductor memory device according to claim 1, wherein each memory transistor 10 comprises a source region contracted to the channel forming region, and a drain region spaced to the source region and contacted to the channel forming region, wherein a plurality of gate electrodes of the plurality of memory transistors are connected to a 15 plurality of word lines,

wherein the source region and drain region of each memory transistor are connected to a common line in a bit direction, electrically insulated to and intersecting to the word line, and

20 wherein said nonvolatile semiconductor memory device further comprises
a write inhibit voltage supply means for supplying a reverse-biased voltage to the source region and/or the drain region of the memory transistor the gate 25 electrode of which is connected to the word line selected

650077-970760

at a writing, through the common line, to make the source region and/or the drain region in a reverse-biased state to the channel forming region, and

5 supplying a voltage to a non-selected word line at the writing, a polarity of the voltage being a polarity making the non-selected word line in a reverse biased state to the channel forming region.

10. A nonvolatile semiconductor memory device according to claim 9, wherein the write inhibit voltage supply means supplies the reverse bias voltage to the source region and/or the drain region to make a bias a voltage of the memory transistor connected to the selected word line to thereby prevent an erroneous write and/or an erroneous erase.

11. A nonvolatile semiconductor memory device according to claim 9, wherein the non-selected word line biasing means supplies a voltage having a polarity for reverse-biasing to the non-selected word line to make a bias a voltage of the memory transistor connected to the non-selected word line to thereby prevent an erroneous write and/or an erroneous erase.

12. A nonvolatile semiconductor memory device according to claim 9, wherein the non-selected word line biasing means biases the gate electrode to the source

region so that a voltage of the gate electrode becomes a low level equal or lower than an inhibit gate voltage.

13. A nonvolatile semiconductor memory device according to claim 9, wherein when the reverse bias 5 voltage is supplied to the channel forming region while the gate electrode and the channel forming region of the memory transistor are kept at a same potential level, depletion layers extend from the source region and drain region to the channel forming region to merge them.

10 14. A nonvolatile semiconductor memory device according to claim 9, wherein the gate length of the memory transistor is shorter than a gate length given by, when the reverse bias voltage is supplied while the gate electrode and the channel forming region are kept at a 15 same potential level, a merged depletion layers extended from the source region and the drain region to the channel forming region.

15. A nonvolatile semiconductor memory device according to claim 1, wherein each memory transistor 20 comprises a source region contacted to the channel forming region, and a drain region spaced to the source region and contacted to the channel forming region, and wherein said nonvolatile semiconductor memory device comprises

25 a source line commonly connecting the plurality

650074-3/207650

of source regions of the plurality of memory transistors
in a bit direction,

a bit line commonly connecting the plurality of
drain regions of the plurality of memory transistors in
5 the bit direction, and

a word line commonly connecting the plurality
of gate electrodes of the plurality of memory transistors
in a word direction.

16. A nonvolatile semiconductor memory device
10 according to claim 1, wherein each memory transistor
comprises a source region contacted to the channel
forming region, and a drain region spaced to the source
region and contacted to the channel forming region,
and wherein said nonvolatile semiconductor
15 memory device comprises
sub source lines commonly connecting the
plurality of source regions of the plurality of memory
transistors in a bit direction,
a main source line commonly connecting the sub
20 source lines in the bit direction,
sub bit lines commonly connecting the plurality
of drain regions of the plurality of memory transistors
in the bit direction,
a main bit line commonly connecting the sub bit
25 line in the bit direction, and

66000000-9707660

a word line commonly connecting the plurality of gate electrodes of the plurality of memory transistors in a word direction,

a selected memory transistor being connected
5 between the sub source line and the main source line and
between the sub bit line and the main bit line.

17. A nonvolatile semiconductor memory device according to claim 1, wherein the plurality of memory transistors are connected in series between a first
10 selected transistor connected to a bit line and a second selected transistor connected to a common potential line.

18. A nonvolatile semiconductor memory device according to claim 1, wherein each memory transistor comprises a source region contacted to the channel
15 forming region, and a drain region spaced to the source region and contacted to the channel forming region,

wherein said nonvolatile semiconductor memory device comprises

a plurality of element separation regions for
20 isolating the respective memory transistors by insulation,

a common line commonly connecting the source regions or the drain regions in a bit direction, and
a word line connecting the plurality of gate electrodes in a word direction,

25

060707-970769

wherein the plurality of element separation regions are formed as lines along the bit direction and spaced each other, and

wherein the common line intersects and is
5 electrically isolated to the word line, is connected to
one of the source region or the drain region, and is
wired on the element separation regions by avoiding a
wiring passing on another region of the source region or
the drain region which is not connected to the common
10 line.

19. A nonvolatile semiconductor memory device according to claim 18, wherein the plurality of element separation regions are formed as parallel strips having a width approximately equal to that of the word line, adjacent strips being spaced as adjacent word lines.

wherein a self-aligned contact hole is formed on the source region and the drain region by using a sidewall insulation layer formed on sidewalls of the word line, and

20 wherein the common line wired on the element
separation regions is commonly connected to the one
region through the self-aligned contact hole and is wired
by a winding manner in the bit direction.

20. A nonvolatile semiconductor memory device
25 according to claim 1, wherein the charge storing means

does not have conductivity as a whole facing to the channel forming region when charges are not moved to the outside of the memory transistor.

21. A nonvolatile semiconductor memory device
5 according to claim 20, wherein the gate insulating film
comprises

a tunneling insulating film formed on the
channel forming region, and

10 a nitride film or an oxide nitride film, formed
on the tunneling insulating film.

22. A nonvolatile semiconductor memory device
according to claim 20, wherein the gate insulating film
comprises

15 a tunneling insulating film formed on the
channel forming region, and
conductors including small sized conductive
material, formed on the tunneling insulating film as the
charge storing means and isolated each other.

23. A process of producing a nonvolatile
20 semiconductor memory device, including the steps of:
forming a drain region, a source region and a
channel forming region arranged between the drain region
and the source region and contacted to them;
forming a gate insulating film including a
25 charge storing means formed on and facing the surface of

the channel forming region; and

forming a gate electrode on the gate insulating film,

said gate insulating film formation step

5 including a step of forming a Fowler-Nordheim (FN) type tunneling film comprising material having an FN tunneling electroconductivity and having a dielectric constant larger than that of silicon oxide, and

10 said FN tunneling film forming step including a step of heating the FN tunneling film at a high temperature under an atmosphere of reduction gas and/or oxidation gas.

24. A process of producing a nonvolatile semiconductor memory device according to claim 23,

15 wherein the FN tunneling film comprises any one of a nitride film, an oxynitride film, and aluminum oxide film, a tantalum pentoxide film and a BST (BaSrTiO₃) film, having an FN tunneling electroconductivity.

25. A process of producing a nonvolatile semiconductor memory device according to claim 23, further including a step of forming a buffer layer formed between the FN tunneling film and the channel forming region and suppressing an interface trap level, before forming the FN tunneling film.

26. A process of producing a nonvolatile

657074-5707360D

semiconductor memory device according to claim 23,
further including a step of forming a Pool-Frenkel (PF)
type film including any one of a nitride film, an
oxynitride film, and aluminum oxide film, a tantalum
5 ptaoxide film and a BST (BaSrTiO₃) film, having an PF
electroconductivity, on the FN tunneling film.

27. A process of producing a nonvolatile
semiconductor memory device according to claim 25,
further including a step of forming a PN film on the FN
10 tunneling film via the buffer layer, said PN film
comprising any one of a nitride film, an oxynitride film,
an aluminum oxide film, a tantalum ptaoxide film and a
BST (BaSrTiO₃) film, having a PF electroconductivity.

28. A method of writing data into a nonvolatile
15 semiconductor memory device, said nonvolatile
semiconductor memory device comprising: a substrate;
a plurality of memory transistors formed in the
substrate and arranged in a word direction and a bit
direction; a pull-up electrode, each memory transistor
20 including: a semiconductor channel forming region formed
in the substrate; a gate insulating film formed on the
semiconductor channel forming region and comprising a
Fowler-Nordheim (FN) type tunneling film which has a FN
type tunneling electroconductivity and contains material
25 having a dielectric constant greater than that of silicon

oxide; a gate electrode formed on the gate insulating film; and a charge storing means, formed in the gate insulating film, and facing to the surface of the channel forming region, said pull-up electrode in the vicinity of 5 the gate electrode or a wiring layer connected to the gate electrode via a dielectric film,

 said writing method including a step of applying a voltage to the pull-up electrode to raise a potential of the gate electrode.

10 29. A method of writing data into a nonvolatile semiconductor memory device, including a step of applying a program voltage equal or lower than 10V, to a gate electrode of the selected memory transistor.

15 30. A method of writing data into a nonvolatile semiconductor memory device, wherein the pull-up electrode is capacitive-coupled to the gate electrode or the wiring layer connected to the gate electrode, via the dielectric film.

20 31. A process of producing a nonvolatile semiconductor memory device according to claim 28, wherein the FN tunneling film comprises any one of a nitride film, an oxynitride film, and aluminum oxide film, a tantalum pentaoxide film and a BST ($BaSrTiO_3$) film, having an FN tunneling electroconductivity.

25 32. A method of writing data into a nonvolatile

semiconductor memory device according to claim 28,
wherein the gate insulating film includes a buffer layer
formed between the FN tunneling film and the channel
forming region and suppressing an interface trap level.

5 33. A method of writing data into a nonvolatile
semiconductor memory device according to claim 28,
wherein the gate insulating film comprises a Pool-Frenkel
(PF) type film including any one of a nitride film, an
oxynitride film, and aluminum oxide film, a tantalum
10 pentaoxide film and a BST (BaSrTiO₃) film, having an PF
electroconductivity.

15 34. A method of writing data into a nonvolatile
semiconductor memory device according to claim 33,
wherein the gate insulating film includes a buffer layer
formed between the FN tunneling film and the PN film.

20 35. A method of writing data into a nonvolatile
semiconductor memory device according to claim 28,
including the steps of:

25 supplying a reverse-biased voltage to the
source region and/or the drain region of the memory
transistor the gate electrode of which is connected to
the word line selected at a writing, through the common
line, to make the source region and/or the drain region
in a reverse-biased state to the channel forming region,
and

supplying a voltage to a non-selected word line at the writing, a polarity of the voltage being a polarity making the non-selected word line in a reverse-biased state to the channel forming region.

5 36. A method of writing data into a nonvolatile
semiconductor memory device according to claim 35,
including a step of supplying the reverse-bias voltage to
the source region and/or the drain region to make a bias
a voltage of the memory transistor connected to the
10 selected word line to thereby prevent an erroneous write
and/or an erroneous erase.

37. A method of writing data into a nonvolatile semiconductor memory device according to claim 35, including a step of supplying a voltage having a polarity 15 for reverse-biasing to the non-selected word line to make a bias a voltage of the memory transistor connected to the non-selected word line to thereby prevent an erroneous write and/or an erroneous erase.

38. A method of writing data into a nonvolatile
20 semiconductor memory device according to claim 35,
including a step of biasing the gate electrode to the
source region so that a voltage of the gate electrode
becomes a low level equal or lower than an inhibit gate
voltage.

39. A method of writing data into a nonvolatile

semiconductor memory device according to claim 35,
wherein when the reverse bias voltage is supplied to the
channel forming region, the gate electrode and the
channel forming region of the memory transistor are
5 applied by a same voltage.

40. A method of writing data into a nonvolatile
semiconductor memory device, wherein the reverse bias
voltage is applied to the source region via a source line
commonly connecting the source regions in the bit
direction, and/or, the drain region via a bit line
10 commonly connecting the drain regions in the bit
direction, and
wherein the voltage having a polarity for
reverse-biasing is applied via the word line commonly
15 connecting the gate electrodes in the word direction.

41. A method of writing data into a nonvolatile
semiconductor memory device according to claim 28,
wherein each memory transistor comprises a source region
contacted to the channel forming region, and a drain
20 region spaced to the source region and contacted to the
channel forming region,

and wherein said nonvolatile semiconductor
memory device comprises
a source line commonly connecting the plurality
25 of source regions of the plurality of memory transistors

06076-9076

in a bit direction,

a bit line commonly connecting the plurality of drain regions of the plurality of memory transistors in the bit direction, and

5 a word line commonly connecting the plurality of gate electrodes of the plurality of memory transistors in a word direction.

42. A method of writing data into a nonvolatile semiconductor memory device according to claim 28,

10 wherein each memory transistor comprises a source region contacted to the channel forming region, and a drain region spaced to the source region and contacted to the channel forming region,

15 and wherein said nonvolatile semiconductor memory device comprises

sub source lines commonly connecting the plurality of source regions of the plurality of memory transistors in a bit direction,

20 a main source line commonly connecting the sub source lines in the bit direction,

sub bit lines commonly connecting the plurality of drain regions of the plurality of memory transistors in the bit direction,

25 a main bit line commonly connecting the sub bit line in the bit direction, and

661074-5707600

a word line commonly connecting the plurality of gate electrodes of the plurality of memory transistors in a word direction,

5 a selected memory transistors being connected between the sub source and the main source line and between the sub bit line and the main bit line.

43. A method of writing data into a nonvolatile semiconductor memory device according to claim 28, wherein the plurality of memory transistors are connected 10 in series between a first selected transistor connected to a bit line and a second selected transistor connected to a common potential line.

44. A method of writing data into a nonvolatile semiconductor memory device according to claim 28, 15 wherein each memory transistor comprises a source region contacted to the channel forming region, and a drain region spaced to the source region and contacted to the channel forming region,

wherein said nonvolatile semiconductor memory 20 device comprises

a plurality of element separation regions for isolating the respective memory transistors by insulation,

25 a common line commonly connecting the source regions or the drain regions in a bit direction, and

a word line connecting the plurality of gate electrodes in a word direction,

wherein the plurality of element separation regions are formed as lines along the bit direction and 5 spaced each other, and

wherein the common line intersects and is electrically isolated to the word line, is connected to one of the source region or the drain region, and is wired on the element separation regions by avoiding a 10 wiring passing on another region of the source region or the drain region which is not connected to the common line.

45. A method of writing data into a nonvolatile semiconductor memory device according to claim 44, 15 wherein the plurality of element separation regions are formed as parallel strips having a width approximately equal to that of the word line, adjacent strips being spaced as adjacent word lines,

wherein a self-aligned contact hole is formed 20 on the source region and the drain region by using a sidewall insulation layer formed on sidewalls of the word line, and

wherein the common line wired on the element 25 separation regions is commonly connected to the one region through the self-aligned contact hole and is wired

by a manner in the bit direction.

46. A method of writing data into a nonvolatile semiconductor memory device according to claim 28, wherein the charge storing means does not have 5 conductivity as a whole facing to the channel forming region when charges are not moved to the outside of the memory transistor.

47. A method of writing data into a nonvolatile semiconductor memory device according to claim 46, 10 wherein the gate insulating film comprises a tunneling insulating film formed on the channel forming region, and a nitride film or an oxide nitride film, formed on the tunneling insulating film.

48. A method of writing data into a nonvolatile semiconductor memory device according to claim 46, wherein the gate insulating film comprises 15 a tunneling insulating film formed on the channel forming region, and conductors including small sized conductive material, formed on the tunneling insulating film as the charge storing means and isolated each other.

49. A method of writing data into a nonvolatile semiconductor memory device according to claim 28, 25 wherein a program voltage is applied to the gate

DATAFILE: 32075760

electrode, and

a voltage is applied to the pull-up electrode
of the selected memory transistor.

50. A method of writing data into a nonvolatile
5 semiconductor memory device according to claim 35,
wherein a voltage having a polarity for reverse-biasing
is applied to the non-selected word line,

the reverse-biasing voltage is applied to the
source region and/or the drain region of the memory
10 transistor connected to the selected word line,

a program voltage is applied to the selected
word line, and

a voltage is applied to the pull-up electrode.

51. A method of writing data into a nonvolatile
15 semiconductor memory device according to claim 50,
wherein a selected memory transistor is connected to the
word line and,

20 a selected memory transistor connected to a
selected word line is controlled in a non-conductive
state when the voltage is applied to the pull-up
electrode.

NONVOLATILE SEMICONDUCTOR MEMORY DEVICE AND PROCESS OF
PRODUCTION AND WRITE METHOD THEREOF

5

ABSTRACT OF THE DISCLOSURE

A nonvolatile semiconductor memory device
featuring a reducing operating voltage while maintaining
a good disturbance characteristic and high speed in a
10 write operation, including a gate insulating film and
gate electrode stacked on a channel forming region of a
semiconductor provided on the surface of a substrate and
planarily dispersed charge storing means such as carrier
traps in a nitride film or near the interface with the
15 top insulating film, provided in the gate insulating
film, the gate insulating film including an FN tunnel
film having a dielectric constant larger than that of a
silicon oxide film and exhibiting an FN
electroconductivity, whereby the thickness of the gate
20 insulating film, converted to that of a silicon oxide
film, can be reduced and the voltage can be reduced.
Further, to reduce the operation voltage, it is possible
to provide a pull-up electrode near the gate electrode
through the dielectric film and pull-up gate bias circuit
25 supplying a predetermined voltage to the same and boost

00000000000000000000000000000000

the gate electrode by capacity coupling.

DECLARATION AND POWER OF ATTORNEY FOR PATENT APPLICATION**English Language Declaration**

As below named inventors, we hereby declare that:

Our residence, post office address and citizenship are as stated below next to our names.

NONVOLATILE SEMICONDUCTOR MEMORY DEVICE AND PROCESS OF PRODUCTION AND WRITE METHOD THEREOF

We believe we are the original, first and joint inventors of the subject matter which is claimed and for which a patent is sought on the invention entitled

the specification of which

(check one)

is attached hereto.

was filed on _____ as

Application Serial No. _____ and was amended on _____

I hereby state that I have reviewed and understand the contents of the above identified specification, including the claims, as amended by any amendment referred to above.

I acknowledge the duty to disclose information which is material to patentability as defined in Title 37, Code of Federal Regulations, §1.56.

I hereby claim foreign priority benefits under Title 35, United States Code, §119 of any foreign application(s) for patent or inventor's certificate listed below and have also identified below any foreign application for patent or inventor's certificate having a filing date before that of the application on which priority is claimed:

Prior Foreign Application(s)

Priority Claimed

<u>P10-313734</u>	<u>JAPAN</u>	<u>04/11/1998</u>	<input checked="" type="checkbox"/> Yes	<input type="checkbox"/> No
